

Wifi and Bluetooth: This is what enables the Pi to connect wirelessly to wifi and bluetooth, etc. This is a small, onboard PCB antenna that is built into the Pi, although for better connection, you can use an external USB Wifi adaptor.

Pins: these are currently being used to connect to a larger board. These allow the Pi to talk to sensors, send power, or control electronic parts.

RAM: stands for Random Access Memory. This is short-term memory and can hold data that you're currently using

Ethernet: Ethernet is basically a cord that sends data between machines that are connected. It is considered to be faster, more stable, and more secure than sending the data using a wireless connection.

USB ports: helps the Pi connect to keyboards, mice, other computers, etc to send data or power. Uses wires.

Camera: takes pictures and video.

Micro HDMI ports: Another way to connect the Pi to other computers/etc. I used it to connect to the monitor.

USB-C port: Similar to the Micro HDMI, except USB-C, and I used this port to provide power.

Processor: This is the Pi equivalent of a brain for a human. It can run the OS, execute programs and commands, process user inputs, do tasks requiring math and logic, and facilitate communication with the other parts of the Pi.

SD card: This stores the OS, saved programs and apps, and saved files and documents. Really important. Without it, the Pi won't work.
